

# Model checking for Self-Replicating Robotic Systems

Student: Dmitry Babaytsev

Referees: Prof. Dr. Jan Oliver Ringert  
PD Dr. Andreas Jakoby

4 November 2025

# Introduction

This work investigated the application of automated model checking to the domain of self-replicating robotic systems (SRRS).

The structure of the presentation:

- SRRS domain background
- Model checking background
- Research questions and the subject SRRS
- Simulation platform
- Implementation of model checking aspects to SRRS
- Threats to validity
- Conclusion

# Self-replicating robotic systems

**A self-replicating robotic system** is a system capable of creating an identical or very similar copy of itself using available resources, without significant changes to its design or structure.

## Formal description

Von Neumann:

$$(A + B + C + D) \rightarrow (A + B + C + D), (A + B + C + D)$$

A - constructor

B - copier

C - controller

D - instructions

Degree of self-replication:

$$DOSR = \frac{\text{System Complexity}}{\text{Parts Complexity}}$$

G.S. Chirikjian:

$$(R, M, E) \rightarrow (R', M', E')$$

$$(R', M', E') = \Phi(R, M, E, t)$$

$R$  - functional system to be reproduced

$M$  - multiset of available parts

$E$  - environmental structures

$R'$ ,  $M'$ ,  $E'$ , the replicated entities, the remaining or altered material and the possibly changed environment respectively.

# Self-replicating robotic systems

**A self-replicating robotic system** is a system capable of creating an identical or very similar copy of itself using available resources, without significant changes to its design or structure.

## Classification of replication process

### Centralized

### Decentralized

### Hierarchical

# Self-replicating robotic systems

**A self-replicating robotic system** is a system capable of creating an identical or very similar copy of itself using available resources, without significant changes to its design or structure.

## Classification of replication process

# Model checking

Model checking is a formal verification method used to automatically determine whether a model of a system satisfies a given specification.

Models  $M$  - transition systems

Properties  $\phi$  - formulas in temporal logic.

| Operator   | Symbol        | Meaning                                                  |
|------------|---------------|----------------------------------------------------------|
| Next       | $X \phi$      | $\phi$ holds in the <b>next</b> state                    |
| Eventually | $F \phi$      | $\phi$ will hold <b>sometime in the future</b>           |
| Always     | $G \phi$      | $\phi$ holds <b>at all future times</b>                  |
| Until      | $\phi U \psi$ | $\phi$ holds <b>until</b> $\psi$ becomes true            |
| Release    | $\phi R \psi$ | $\psi$ must hold <b>until and including</b> $\phi$ holds |

# Model checking

Model checking is a formal verification method used to automatically determine whether a model of a system satisfies a given specification.

Models  $M$  - transition systems

Properties  $\phi$  - formulas in temporal logic.

| Operator                           | Symbol            | Meaning                                                    |
|------------------------------------|-------------------|------------------------------------------------------------|
| <b>AX <math>\phi</math></b>        | $A X \phi$        | $\phi$ holds in the <b>next state of all paths</b>         |
| <b>EX <math>\phi</math></b>        | $E X \phi$        | $\phi$ holds in the <b>next state of some path</b>         |
| <b>AF <math>\phi</math></b>        | $A F \phi$        | On <b>all paths</b> , $\phi$ will eventually hold          |
| <b>EF <math>\phi</math></b>        | $E F \phi$        | There <b>exists a path</b> where $\phi$ eventually holds   |
| <b>AG <math>\phi</math></b>        | $A G \phi$        | On <b>all paths</b> , $\phi$ holds globally (always)       |
| <b>EG <math>\phi</math></b>        | $E G \phi$        | There <b>exists a path</b> where $\phi$ always holds       |
| <b>A[<math>\phi U \psi</math>]</b> | $A (\phi U \psi)$ | On <b>all paths</b> , $\phi$ holds until $\psi$            |
| <b>E[<math>\phi U \psi</math>]</b> | $E (\phi U \psi)$ | There <b>exists a path</b> where $\phi$ holds until $\psi$ |

# Research questions

1. How can automated model checking be used to verify different properties of self-replicating robotic system, and what adaptations can be done for practical implementation?
2. What systematic methodology can translate the behaviors and structural constraints of self-replicating robots into formal models and temporal-logic specifications?
3. What limitations – computational, semantic, or modelling-related – does model checking face in domain of SRRS, and how these limitations can be mitigated?

# Analysis of the applicability of model checking to SRRS

Cases:

1. Check local reachability of some point or a set of points (region) by the robot end-effector.
2. Research global reachability of some point or region by robot end-effector using Implementation of model checking in SRRS the walking form of movements.
3. Analyze set of robot configurations – check existing configuration or find relevant configurations of blocks based on counterexamples.

Usage of the counterexample

# Threats to validity

1. **Limited generalization of the developed system:**  
the applicability of the proposed verification methods is confined to a specific class of SRRS systems (direct self-replication of modular robots).
2. **Discretization errors and computational trade-offs:**  
the accuracy and performance of the model are constrained by the discretization parameter.
3. **Inconsistencies between NuSMV models, simulation environments, and real world:**  
abstractions and simplifications lead to mismatches between modeled and physical behaviors.

# Conclusion

1. Demonstrated how model checking can be applied to verify three aspects of SRRS behavior. Each aspect corresponds to a reachability checking on different level of system abstraction:

- Local
- Global
- Structural

2. Provided a framework for integrating formal verification in the domain of SRRS:

- Extendable NuSMV robot, model that can be used to verify different aspects of reachability.
- Python modules for NuSMV model generation for different configurations of modular robot.
- Simulation platform based on ROS2–Gazebo implementation of a modular SRRS.
- NuSMV counterexample based control

3. Described computational and modelling-related limitations of model, and how they can be mitigated

## Future work :

- Model checking of other kinds of robots, material, and environments.
- Higher-level controllers capable of using counterexamples to dynamically guide assembly.
- Adaptive verification that allows the robot to modify its configuration based on environments.
- Extending the framework to collective SRRS, involving cooperate of multiple robots.
